

SOLUTION

1. Create or load a dataset containing input features and target classes.
2. Divide the data into training and testing sets.
3. Create a Decision Tree Classifier.
4. Train the classifier using the training data.
5. The algorithm selects the best feature for splitting the data.
6. Continue splitting until suitable leaf nodes are formed.
7. Use the trained tree to predict the class of test data.
8. Calculate the accuracy of the model.
9. Display the predictions and accuracy.
